

# **Operator Overloading and Type Conversions**

# Introduction

- It is one of the many exciting features of C++.
- C++ has ability to provide the operators with a special meaning for a data types.
- We can overload (give additional meaning to) all the C++ operators except:
  - Class member access operators ( . & .\* )
  - Scope resolution operators ( :: )
  - Size operator (sizeof)
  - Conditional operators ( ? : )
- When an operator is overloaded, its original meaning is not lost.

# Defining Operator Overloading

- To define an additional task to an operator, we must specify what it means in relation to the class to which the operator is applied.
- This is done with the help of a special function called *operator function*.

```
return type class-name : :operator op (arg-list)
```

```
{
```

```
    Function body // task defined
```

```
}
```

# Defining Operator Overloading

```
return type class-name : :operator op (arg-list)
{
    Function body // task defined
}
```

- ***return type*** is the type of value returned by the specified operation.
- ***op*** is the operator being overloaded.
- ***op*** is preceded by the keyword **operator**.
- ***operator op*** is the function name.

# Defining Operator Overloading

continue...

Operator Function must be either

- member function (non-static)

Or

- friend function.

The basic difference :

- A friend function will have only one argument for unary operators and two for binary operators.
- A member function has no arguments for unary operators and one argument for binary operators.
- This is because the object used to invoke the member function is passed implicitly and therefore is available for the member function.
- Arguments may be passed either by value or by reference.

# Process of Operator Overloading

The process of overloading involves the following steps:

- Create a class that defines the data type that is to be used in the overloading operation.
- Declare the operator function ***operator op()*** in the public part of the class. It may be either a member function or a friend function.
- Define the operator function to implement the required operations.

# Process of Operator Overloading

Overloaded operator functions can be invoked by expressions such as:

For unary operators:  $op\ x$  or  $x\ op$

For binary operators:  $x\ op\ y$

$op\ x$  or  $x\ op$  would be interpreted as

for a friend function:  $operator\ op\ (x)$

for a member function:  $x.operator\ op\ ( )$

$x\ op\ y$  would be interpreted as

for a friend function:  $operator\ op\ (x,y)$

for a member function:  $x.operator\ op\ (y)$

# Overloading Unary Operators

Consider a unary minus operator:

- It takes just one operand.
- It changes the sign of an operand when applied to a basic data item.
- The unary minus when applied to an object should change the sign of each of its data items.

# Overloading Binary Operators

As a rule, in overloading binary operators,

- the *left-hand* operand is used to invoke the operator function and
- the right-hand operand is passed as an argument.

# Overloading Binary Operators

```
return complex((x+c.x), (y+c.y));
```

The compiler invokes an appropriate constructor, initializes an object with no name and returns the contents for copying into an object.

Such an object is called a temporary object and goes out of space as soon as the contents are assigned to another object.

# Overloading Binary Operators Using Friends

- Friend function requires two arguments to be explicitly passes to it.
- Member function requires only one.

```
friend complex operator+(complex, complex);
```

```
complex operator+(complex a, complex b)  
{  
    return complex((a.x + b.x),(a.y + b.y));  
}
```

# Overloading Binary Operators Using Friends

- We can use a friend function with built-in type data as the left-hand operand and an object as the right-hand operand.

# Manipulation of Strings using Operators

- There are lot of limitations in string manipulation in C as well as in C++.
- Implementation of strings require character arrays, pointers and string functions.
- C++ permits us to create our own definitions of operators that can be used to manipulate the strings very much similar to other built-in data types.
- ANSI C++ committee has added a new class called string to the C++ class library that supports all kinds of string manipulations.

# Manipulation of Strings using Operators

continue...

- Strings can be defined as class objects which can be then manipulated like the built-in types.
- Since the strings vary in size, we use new to allocate memory for each string and a pointer variable to point to the string array.

# Manipulation of Strings using Operators

continue...

- We must create string objects that can hold two pieces of information:

- Length
- Location

```
class string
{
    char *p;    // pointer to string
    int  len;    // length of string
public :
    -----
    -----
};
```

# Rules For Overloading Operators

- Only existing operators can be overloaded. New operators cannot be created.
- The overloaded operator must have at least one operand that is of user-defined type.
- We cannot change the basic meaning of an operator.
- Overloaded operators follow the syntax rules of the original operators.

# Rules For Overloading Operators

continue...

- The following operators that cannot be overloaded:
  - Size of    Size of operator
  - .        Membership operator
  - .\*       Pointer-to-member operator
  - ::       Scope resolution operator
  - ? ;      Conditional operator

# Rules For Overloading Operators

continue...

- The following operators can be over loaded with the use of member functions and not by the use of friend functions:
  - Assignment operator =
  - Function call operator( )
  - Subscripting operator [ ]
  - Class member access operator ->
- Unary operators, overloaded by means of a member function, take no explicit arguments and return no explicit values, but, those overloaded by means of a friend function, take one reference argument.

# Rules For Overloading Operators

continue...

- Binary operators overloaded through a member function take one explicit argument and those which are overloaded through a friend function take two explicit arguments.
- When using binary operators overloaded through a member function, the left hand operand must be an object of the relevant class.
- Binary arithmetic operators such as  $+$ ,  $-$ ,  $*$  and  $/$  must explicitly return a value. They must not attempt to change their own arguments.

# Type Conversions

- The type conversions are automatic only when the data types involved are built-in types.  
`int m;`  
`float x = 3.14159;`  
`m = x; // convert x to integer before its value is assigned`  
`// to m.`
- For user defined data types, the compiler does not support automatic type conversions.
- We must design the conversion routines by ourselves.

# Type Conversions

continue...

Different situations of data conversion between incompatible types.

- Conversion from basic type to class type.
- Conversion from class type to basic type.
- Conversion from one class type to another class type.

# Basic to Class Type

A constructor to build a string type object from a  
char \* type variable.

```
string : : string(char *a)
{
    length = strlen(a);
    P = new char[length+1];
    strcpy(P,a);
}
```

The variables length and p are data members of  
the class string.

# Basic to Class Type

continue...

```
string s1, s2;
```

```
string name1 = "IBM PC";
```

```
string name2 = "Apple Computers";
```

```
s1 = string(name1);
```

```
s2 = string(name2);
```

First converts name1 from char\* type to string type and then assigns the string type value to the object s1.

First converts name2 from char\* type to string type and then assigns the string type value to the object s2.

# Basic to Class Type

continue...

```
class time
{
    int hrs ;
    int mins ;
public :
    ...
    time (int t)
    {
        hrs = t / 60 ;
        mins = t % 60;
    }
};
```

```
time T1;
int duration = 85;
```

# Class To Basic Type

A constructor function do not support type conversion from a class type to a basic type.

An overloaded ***casting operator*** is used to convert a class type data to a basic type.

It is also referred to as ***conversion function***.

```
operator typename( )  
{  
    ...  
    ... ( function statements )  
    ...  
}
```

# Class To Basic Type

continue...

```
vector : : operator double( )  
{  
    double sum = 0;  
    for (int i=0; i < size ; i++)  
        sum = sum + v[i] * v[i];  
    return sqrt (sum);  
}
```

This function converts a vector to the square root of the sum of squares of its components.

# Class To Basic Type

continue...

The casting operator function should satisfy the following conditions:

- It must be a class member.
- It must not specify a return type.
- It must not have any arguments.

```
vector : : operator double( )  
{  
    double sum = 0;  
    for (int i=0; i < size ; i++)  
        sum = sum + v[i] * v[i];  
    return sqrt (sum);  
}
```

# Class To Basic Type

continue...

- Conversion functions are member functions and it is invoked with objects.
- Therefore the values used for conversion inside the function belong to the object that invoked the function.
- This means that the function does not need an argument.

# One Class To Another Class Type

`objX = objY ; // objects of different types`

- **objX** is an object of class **X** and **objY** is an object of class **Y**.
- The **class Y** type data is converted to the **class X** type data and the converted value is assigned to the **objX**.
- Conversion is takes place from **class Y** to **class X**.
- **Y** is known as ***source class***.
- **X** is known as ***destination class***.

# One Class To Another Class Type

continue...

Conversion between objects of different classes can be carried out by either a constructor or a conversion function.

Choosing of constructor or the conversion function depends upon where we want the type-conversion function to be located in the source class or in the destination class.

# One Class To Another Class Type

continue...

## operator typename( )

- Converts the class object of which it is a member to typename.
- The typename may be a built-in type or a user-defined one.
- In the case of conversions between objects, typename refers to the destination class.
- When a class needs to be converted, a casting operator function can be used at the source class.
- The conversion takes place in the source class and the result is given to the destination class object

# One Class To Another Class Type

continue...

Consider a constructor function with a single argument

- Construction function will be a member of the destination class.
- The argument belongs to the source class and is passed to the destination class for conversion.
- The conversion constructor be placed in the destination class.
